What is Gonorrhea?
Gonorrhea is a sexually transmitted infection caused by the Neisseria gonorrhoeae bacterium. Nearly a million new gonorrhea infections are reported in the United States every year.

How do you get it?
Gonorrhea is transmitted through vaginal, anal, and oral sex. It is contracted by exposure of a mucous membrane such as the vagina, urethra, anus, and the throat, to an infected person’s mucous membranes or body fluids (e.g., semen, vaginal fluids). You can’t get it from casual contact such as kissing or hugging.

Any sexually active person can get gonorrhea, but people with multiple sexual partners, men who have sex with men, and women under the age of 25 are at higher risk due to increased rates of infection in these groups. Gonorrhea can also be transmitted to an infant during childbirth if the mother is infected.

People who use condoms consistently, who are in mutually monogamous relationships, or who abstain from vaginal, anal, or oral sexual activity are at lower risk for infection.

How would I know if I have it?
Unfortunately, many gonorrhea infections cause no symptoms. In fact, about 50% of infected women and 10% of men (with urethral infections) are asymptomatic. Most men with throat and rectal infections have no symptoms. That’s why it’s so easy to spread the infection without knowing it. If symptoms do occur, they usually start 1–3 weeks after being exposed.

Infected women may notice an abnormal vaginal discharge, pain with urination, lower abdominal pain, pain with sexual activity, fever, or bleeding between menstrual periods.

Men with gonorrhea may develop a discharge from the penis, burning with urination, itching at the tip of the penis, or pain or swelling in the testicles. People who engage in anal sex may notice rectal pain, bleeding or discharge if infected.

How can I get tested?
A simple urine test can detect gonorrhea infections of the penis or vagina, and swab testing can be used for the vagina, throat, and rectum. As many gonorrhea infections have no symptoms, the U.S. Centers for Disease Control and Prevention (CDC) recommend yearly testing for all sexually-active women under age 25, women with new or multiple sex partners, and men who have sex with men. All pregnant women should be screened as part of routine prenatal care.

If you’ve been exposed to gonorrhea, you may have also been exposed to other STIs. Talk with your health care provider about testing for other infections such as gonorrhea, HIV, and syphilis.

• If you have no symptoms, but want a routine gonorrhea or other STI test, call us or visit myCornellHealth to schedule an appointment online with a sexual health nurse.
• If you do have symptoms and/or you believe you have been exposed to gonorrhea, please call (607-255-5155) or visit myCornellHealth for an appointment with your Cornell Health primary care team.

What if I don’t treat the infection?
Untreated gonorrhea in women can result in serious damage to the reproductive organs. It is a common cause of pelvic inflammatory disease (PID), which can scar the fallopian tubes and lead to infertility and ectopic pregnancies in the future.

Untreated gonorrhea in men can cause “epididymitis” (an infection of the tube that carries sperm to the testes) resulting in pain, fever, and —rarely— sterility. If left untreated, gonorrhea can also spread to the blood and cause disseminated gonococcal infection (DGI). DGI is usually characterized by arthritis, inflamed tendons, and/or skin rashes. This condition can be life-threatening.

Additionally, untreated persons can transmit gonorrhea to others, who may also be unaware of their infection, and pass it on further.
How is it treated?
Because gonorrhea is a bacterium, specific antibiotics given by your health care provider usually cure the infection. Both you and any sexual partners you have had contact with in the past 2 months should be treated at the same time. This prevents partners from continuing to re-infect one another. Rectal gonorrhea infections in men who have sex with men can be a warning that you are at high risk for HIV infection. Talk with your primary care provider at Cornell Health about the potential use of preventive medications (HIV PrEP) if you have been diagnosed with rectal gonorrhea.
It’s important that all partners abstain from sexual contact (no oral, vaginal, or anal contact with a partner’s genitals) until at least 7 days after final treatment. If you had symptoms of gonorrhea and they do not go away 1–2 weeks after treatment, another medical evaluation is necessary. Previous infection with gonorrhea does not confer immunity, and so individuals can be infected again if re-exposed.

How do I find out more?
Talk with your health care provider about concerns or questions you may have. Online information can be found at:
